### Abstract

Sulfur fluorides SF<sub>6</sub>, ClSF<sub>5</sub> and CF<sub>3</sub>SF<sub>5</sub> were reacted with C<sub>6</sub>H<sub>6</sub>, C<sub>6</sub>H<sub>5</sub>Br and C<sub>6</sub>H<sub>5</sub>Cl in a low temperature radio-frequency plasma. Due to the stepwise dissociation of sulfur fluorides, the fluorination of benzenes was observed. In all reaction products C<sub>6</sub>H<sub>5</sub>SF<sub>5</sub> was found in minor quantities, and BrC<sub>6</sub>H<sub>4</sub>SF<sub>5</sub> or ClC<sub>6</sub>H<sub>4</sub>SF<sub>5</sub> along with numerous halogenated benzenes when C<sub>6</sub>H<sub>5</sub>Br or C<sub>6</sub>H<sub>5</sub>Cl were used as reactants, respectively.

### Introduction

The introduction of a pentafluorosulfanyl group, SF<sub>5</sub>, into organic molecules can substantially change their properties, which makes compounds containing the SF<sub>5</sub> group potentially useful in a number of applications.<sup>1-6</sup> Incorporating the pentafluorosulfanyl group instead of the trifluoromethyl group into high temperature polyimides may cause these polymers to show enhanced properties such as a lower dielectric constant, greater solubility, increased hydrophobicity, less colour and improved tensile properties.<sup>3</sup> In the field of energetic materials the potential application of SF<sub>5</sub> containing compounds includes the reduction of shock sensitivity of energetic materials in which the nitro group has been replaced by the pentafluorosulfanyl group.<sup>6</sup> The use of pentafluorosulfanylbenzenes has been inhibited by their low yields of production and for this reason many attempts have been made to improve the yields of syntheses and make the compounds available on a large scale.

The first to prepare C<sub>6</sub>H<sub>5</sub>SF<sub>5</sub> was Sheppard<sup>7</sup> in 1960. He isolated several pentafluorosulfanylbenzenes by fluorination of aromatic disulfides with AgF<sub>2</sub> in CFC 113 at 393 K. Pentafluorosulfanylbenzenes were later prepared by various reactions: by the reaction of S<sub>2</sub>F<sub>10</sub> with benzene<sup>8</sup> at 453 K, by the reaction of SF<sub>5</sub>C≡CH with 1,3-butadiene,<sup>9</sup> by the reaction of SF<sub>5</sub>C≡CH with SF<sub>5</sub>Cl,<sup>10</sup> by fluorination of aromatic disulfides in concentrated sulfuric acid,<sup>11</sup> by fluorination of aromatic disulfides with elemental fluorine in CH<sub>3</sub>CN<sup>12</sup> (C<sub>6</sub>H<sub>5</sub>SF<sub>5</sub>, 38.5% yield) and by fluorination of

diphenyl disulfide by  $\text{XeF}_2$ <sup>13,14</sup> ( $\text{C}_6\text{H}_5\text{SF}_5$ , 25% yield). The disadvantage of these methods is the low yield of pentafluorosulfanylbenzenes and the presence of impurities which are difficult to separate from the main product.

Even though different approaches to synthesis have been used, there were so far no reports on reactions in a plasma, which would yield pentafluorosulfanylbenzenes. However, trifluoromethylbenzene,  $\text{C}_6\text{H}_5\text{CF}_3$  was found to form in a low temperature plasma of gases  $\text{C}_6\text{H}_5\text{Br}$  and  $\text{C}_2\text{F}_6$ .<sup>15</sup> By using reactive  $\text{CF}_3\cdot$  radicals generated in a low temperature plasma from  $\text{C}_2\text{F}_6$  gas, numerous organometallic compounds were also prepared.<sup>16</sup> Similarly,  $\text{SF}_5\cdot$  radicals generated in a plasma would be expected to react with benzenes to produce pentafluorosulfanylbenzenes. The present work was aimed at the plasma chemistry of the sulfur fluorides  $\text{SF}_6$ ,  $\text{CF}_3\text{SF}_5$ ,  $\text{ClSF}_5$  and benzenes, with special emphasis on the formation of pentafluorosulfanylbenzenes in the plasma.

### Experimental

**Reagents.** Benzene (analytical grade) was obtained from Kemika,  $\text{C}_6\text{H}_5\text{Br}$  (99%) and  $\text{C}_6\text{H}_5\text{Cl}$  (99.9%) from Aldrich.  $\text{SF}_6$  (99.75%) from Aldrich and  $\text{CF}_3\text{SF}_5$  from Flura Corporation were used as received.  $\text{ClSF}_5$  was prepared by the reaction of  $\text{SF}_4$ ,  $\text{Cl}_2$  and dry  $\text{CsF}$  in a stainless steel pressure reaction vessel which was gradually heated to 448 K during a 3 hour period and then kept at this temperature for 2 hours.<sup>17</sup>  $\text{C}_6\text{H}_5\text{SF}_5$  which was used as a standard sample, was prepared by two different methods.<sup>7,14</sup>

**Apparatus.** The source of radio-frequency power was an IEVT VGK 200/1 high frequency generator operating at 27 MHz and at 300 W maximum power. The power dissipated in the plasma reactors was measured by a Zetagi HP 201 SWR through-line wattmeter.

Reactions were carried out in a bell jar type quartz reactor described elsewhere<sup>18</sup> and in a stainless steel reactor.<sup>19</sup> The quartz reactor was a 70 mm o.d., 250 mm long quartz tube, connected on one side by two inlet tubes to gas cylinders with flow regulators, and on the other side to a cold trap held at 77 K, which was evacuated by a diffusion pump. The plasma was inductively coupled through a helical coil, which consisted of seven

turns of 4 mm o.d. copper tubing. The pressure inside the reactor was monitored by an ILM Labor Pirani vacuummeter and the power dissipated in the reactor was 15 W.

Stainless steel reactor was an in house constructed modified GEC reference cell<sup>19,20</sup> of 200 mm i.d. and 284 mm in height. Gases were supplied to the reactor from gas cylinders and the flow was controlled by MKS 1359 CJ Mass Flow Controllers. The pressure in the reactor was measured by an MKS Baratron pressure meter (0-100 Pa) and by an in-house Alpert gauge high vacuum and ultra high vacuum meter. The plasma in the reactor was inductively coupled through a silica window by a five-turn planar coil of 3 mm diameter<sup>21</sup> and the power dissipated in the reactor was 25 W.

**Methods.** *Reactions in a low temperature plasma.* Prior to reactions in a low temperature plasma, the system (all quartz or stainless steel) was evacuated to  $10^{-3}$  Pa and a Dewar flask with liquid nitrogen was placed around the trap. The flow rates of gases were adjusted to the required values. After the flow and pressure stabilized, the plasma was initiated. Reaction products were trapped in the 77 K trap and were subsequently separated on a vacuum line into two fractions: low boiling and high boiling fractions. Low boiling fraction was analysed by FTIR while high boiling fraction was analyzed by GC–MS and by GC–FTIR. Chromatographically separated compounds were identified by comparing the mass spectra and IR spectra of individual components to NIST library mass spectra<sup>22</sup> and to Aldrich library FTIR spectra, respectively.<sup>23,24</sup>

In the quartz reactor sulfur fluorides  $\text{SF}_6$  and  $\text{CF}_3\text{SF}_5$  were reacted with  $\text{C}_6\text{H}_6$ ,  $\text{C}_6\text{H}_5\text{Br}$  and  $\text{C}_6\text{H}_5\text{Cl}$  at a total flow rate of  $1 \text{ mL min}^{-1}$  to  $11.3 \text{ mL min}^{-1}$  in individual experiments. Reactions of  $\text{SF}_6$ ,  $\text{CF}_3\text{SF}_5$  and  $\text{ClSF}_5$  with benzene were performed in the stainless steel reactor at a total flow rate of  $7 \text{ mL min}^{-1}$  and argon was added at a flow rate of  $1 \text{ mL min}^{-1}$  to the stainless steel reactor only to facilitate the excitation of species in the plasma.<sup>25</sup> In the quartz reactor the pressure during reactions was kept at 5 Pa, while in the stainless steel reactor the pressure was varied from 1.4 Pa to 14 Pa in individual experiments. The pressure and the radio-frequency power were kept low due to the extensive polymerization of aromatics that occurred at higher applied pressure and radio-frequency power,<sup>26</sup> especially when benzene was used as reactant.

*Degree of dissociation–decomposition of SF<sub>6</sub> in plasma.* For the production of pentafluorosulfanylbenzenes a high dissociation–decomposition of sulfur fluorides in the plasma, which means a high concentrations of SF<sub>5</sub> radicals, is essential. Therefore, the degree of dissociation–decomposition of SF<sub>6</sub> in the stainless steel reactor was determined by the online Dupont instruments quadrupole mass spectrometer 21-440 Residual Gas Analyzer (RGA) which was connected to one of the reactor windows and operated at an ionization energy of 70 eV. Scans from m/z 1 to m/z 200 were completed in 15 seconds. Reaction mixtures were sampled through a 0.05 mm orifice. A separate oil diffusion pump maintained the vacuum in the mass spectrometer at 10<sup>-4</sup> Pa. The degree of dissociation–decomposition of SF<sub>6</sub> gas in a low temperature plasma in a particular stainless steel reactor was determined by the difference mass spectrum which was obtained by recording the mass spectra of SF<sub>6</sub> gas in the stainless steel reactor by the online spectrometer when the discharge was on and at essentially the same conditions when the discharge was off, and subtracting the spectra.<sup>27</sup> Difference mass spectra offer an estimation of the lower and upper limits of the degree of dissociation of the gas in the plasma.

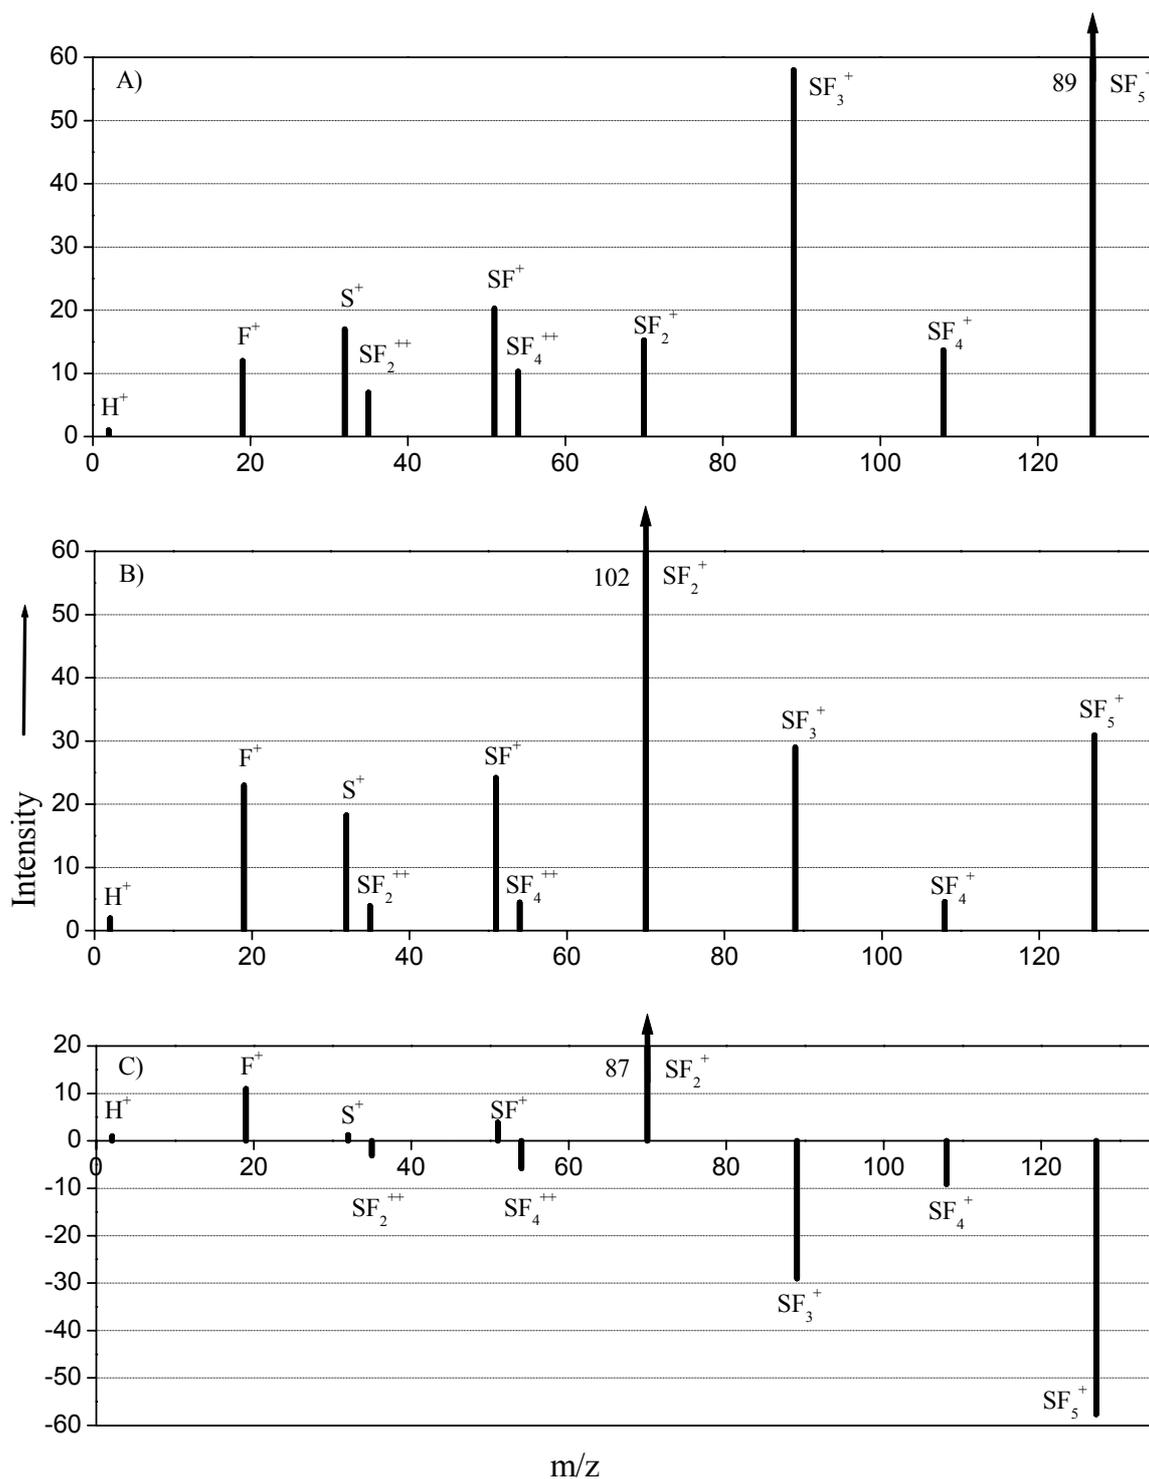

*Analyses.* The direct GC-MS analysis of reaction products trapped at 77 K was carried out on an AutoSpec mass spectrometer (Micromass, Manchester, UK) coupled with an HP 5890 series gas II. chromatograph (Hewlett-Packard, Valdbron, Ge). An HP-5MS 30 m x 0.25 mm fused silica capillary column was used. Splitless injection (splitless duration 60 s) was carried out with an injector temperature of 523 K. The column was held at 323 K during injection and then programmed to the temperature of 473 K at 20 K min<sup>-1</sup>, and to 523 K at 15 K min<sup>-1</sup>. The final column temperature of 573 K was reached at 10 K min<sup>-1</sup>. Helium at a flow rate of 1 mL min<sup>-1</sup> was used as carrier gas. The ionization energy was 70 eV and source electron current was 150 μA. Data were acquired in the magnet scan mode using a scan from m/z 50 to m/z 500 with a scan time of 0.8 s. GC-FTIR analyses were performed on a Model 8700 gas chromatograph coupled with a GC-IR interface to a 1710 FTIR spectrometer (all components from Perkin-Elmer). A Perkin-Elmer bonded methyl 5% phenyl silicone 10 m x 0.53 mm fused silica capillary column with 5 μm film thickness was used. Liquid

samples of 1-2  $\mu\text{l}$  were injected into a packed column injector heated to 523 K. The column was held at 313 K for 5 minutes after injection, then programmed to 493 K at 10  $\text{K min}^{-1}$  and held at 493 K for 2-20 minutes. Helium was used as carrier gas. Components were detected by FID or TCD. Throughout the analyses the transfer line to the FTIR spectrometer and the gold coated light-pipe were heated to 513 K. Spectra were taken at 8  $\text{cm}^{-1}$  resolution.

### Results and discussion

*Determination of dissociation–decomposition rate in a plasma of SF<sub>6</sub> gas.* The concentration of SF<sub>5</sub><sup>·</sup> radicals in a plasma is closely related to the dissociation–decomposition rate of sulfur fluoride gas.<sup>28</sup> The differences in the mass spectra obtained with and without operation of the discharge were used to estimate the degree of dissociation–decomposition of SF<sub>6</sub> in the discharge.<sup>27</sup> Figure 1 shows mass spectra of plasma gases sampled online from the reactor and measured by quadrupole mass spectrometer. The mass spectrum in Figure 1A presents dissociation of SF<sub>6</sub> in the reactor when the discharge is off. The predominance of SF<sub>5</sub><sup>+</sup> followed by SF<sub>3</sub><sup>+</sup> is evident. The mass spectrum observed when the discharge is turned on is shown in Figure 1B. The predominant ion observed at rf discharge conditions is SF<sub>2</sub><sup>+</sup>, which indicates the extensive further stepwise dissociation of sulfur fluoride species SF<sub>5</sub><sup>·</sup>. In addition to the main ions SF<sub>2</sub><sup>+</sup>, SF<sub>3</sub><sup>+</sup> and SF<sub>5</sub><sup>+</sup> measurable contributions to the total ion current from other ions derived directly or indirectly from SF<sub>6</sub>, namely SF<sub>4</sub><sup>+</sup>, SF<sup>+</sup>, F<sup>+</sup> and the doubly charged ions SF<sub>2</sub><sup>2+</sup> and SF<sub>4</sub><sup>2+</sup>, are evident. A reduction in the relative intensities of the ions SF<sub>5</sub><sup>+</sup> and SF<sub>3</sub><sup>+</sup> is observed. The differential mass spectrum in Figure 1C was formed by subtracting the intensity of ion current of products in Figure 1B from the intensity of ion current of products in Figure 1A.

The degree of dissociation of SF<sub>6</sub> in a stainless steel reactor at a SF<sub>6</sub> flow rate of 2.5

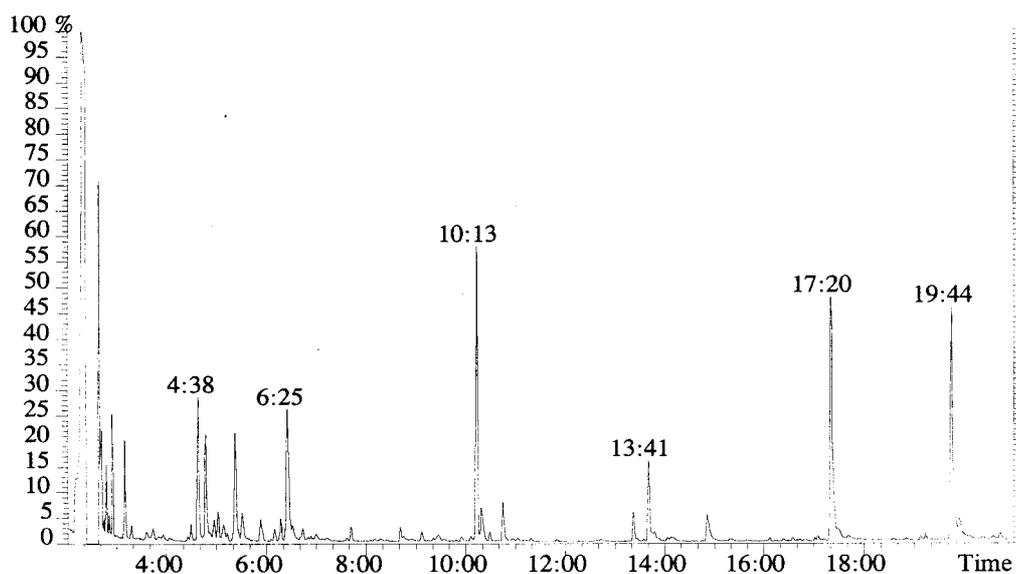

**Figure 1.** Mass spectra of neutral species in SF<sub>6</sub> gas sampled at a pressure of 1.4 Pa: A) SF<sub>6</sub> gas sampled from the cell without discharge, B) SF<sub>6</sub> gas sampled from the cell with discharge on, and C) difference of mass spectra B) and A) where negative values indicate a loss when the plasma is on. The isotope peaks for sulfur containing ions were removed to simplify the spectra.

mL min<sup>-1</sup> and at a pressure of 1.4 Pa (Figure 1) was found to be in the range<sup>27</sup> from 50% to 60%.

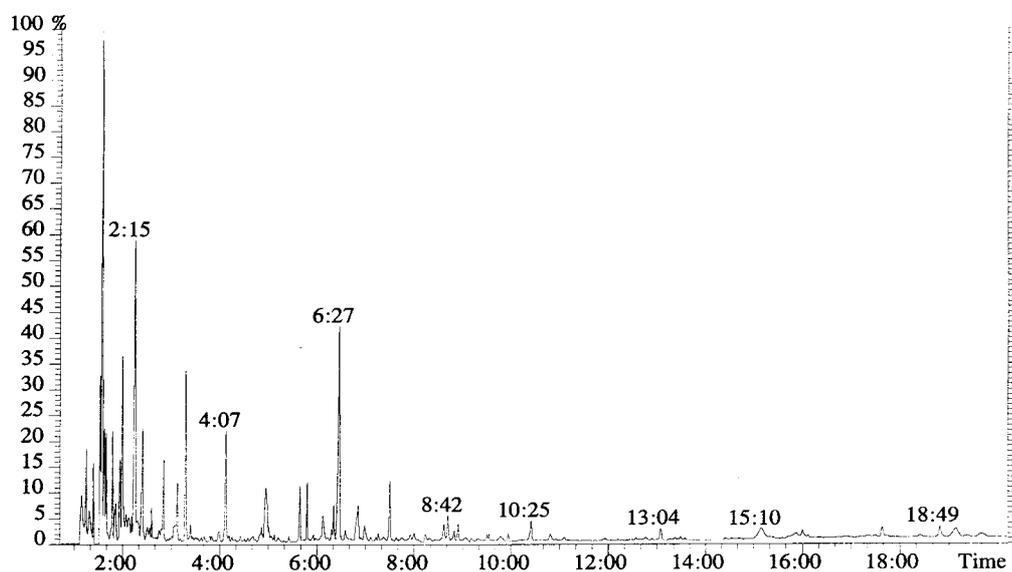

*Reactions of sulfur fluorides and benzenes.* In a low temperature plasma sulfur fluorides SF<sub>6</sub> and CF<sub>3</sub>SF<sub>5</sub> were allowed to react with C<sub>6</sub>H<sub>6</sub>, C<sub>6</sub>H<sub>5</sub>Br and C<sub>6</sub>H<sub>5</sub>Cl in the bell jar reactor (Table 1), and reactions of SF<sub>6</sub>, CF<sub>3</sub>SF<sub>5</sub> and ClSF<sub>5</sub> with benzene were performed in the stainless steel reactor (Table 2), while argon was added to the stainless steel reactor only to facilitate the excitation of species in the plasma.<sup>25</sup>

The composition of low boiling volatile products was determined by GC-MS and GC-FTIR. The GC-MS ion current traces of the condensed extract of the organic compounds from the two reactors are presented in the chromatograms shown in Figures 2 and 3. Mainly halogenated aromatic compounds were identified. Identification of compounds was confirmed by the mass spectra library search and by comparison with pure standards. Some of unknown chromatographic peaks were elucidated by interpretation of the mass spectra of unknowns.<sup>29</sup> Aromatic compounds usually exhibit intensive molecular ion and typical fragment ions, which allow interpretation of unknowns. As an illustration the mass spectrum of the target compound C<sub>6</sub>H<sub>5</sub>SF<sub>5</sub>, formed in reaction between CF<sub>3</sub>SF<sub>5</sub> and benzene in a low temperature plasma is shown in Figure 4.

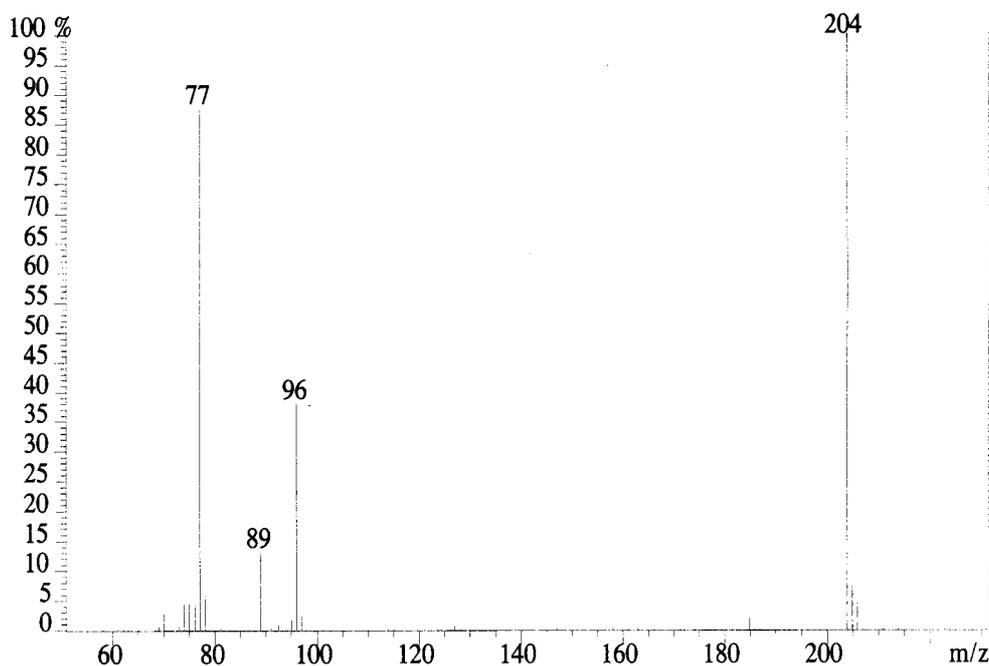

*Reactions in the all quartz bell jar reactor.* Reaction with the quartz wall was observed in the bell jar reactor when SF<sub>6</sub> was used as the source of SF<sub>5</sub><sup>·</sup> radicals; other volatile products determined by IR spectroscopy were SiF<sub>4</sub>, SOF<sub>4</sub> and SO<sub>2</sub>F<sub>2</sub> besides unreacted SF<sub>6</sub>. Less volatile products separated by condensation at 253 K were composed mainly of several classes of halogenated benzenes (Table 1), while pentafluorosulfanylbenzene was determined in traces by GC-MS analysis. SF<sub>6</sub> is an extremely stable molecule and its primary bond dissociation energy<sup>30</sup> of 420 kJ mol<sup>-1</sup> is higher than of other sulfur fluoride primary bond dissociation energies (SF<sub>5</sub>, 222 kJ mol<sup>-1</sup>; SF<sub>4</sub>, 352 kJ mol<sup>-1</sup>; SF<sub>3</sub>, 264 kJ mol<sup>-1</sup>; SF<sub>2</sub>, 384 kJ mol<sup>-1</sup>; SF, 340 kJ mol<sup>-1</sup>).<sup>31</sup> Therefore, the energy required to dissociate the SF<sub>6</sub> molecule also causes the further stepwise dissociation of sulfur species SF<sub>5</sub>, and consequently the fluorination of

**Figure 4.** Mass spectrum of  $C_6H_5SF_5$  found in the reaction products of  $CF_3SF_5$  with  $C_6H_6$  in a plasma.

aromatic species is likely to occur. Benzene excited in a plasma undergoes two main reactions: monomolecular decomposition and bimolecular reaction with neutral molecules.<sup>32</sup> The latter reaction explains the relatively high amount of biphenyl and halogenated biphenyl derivatives in the reaction products.

A plasma containing sulfur fluorides and benzenes together has an extraordinarily complex reaction scheme.<sup>26</sup> In the reaction products of  $CF_3SF_5$  with  $C_6H_6$  and  $C_6H_5Br$ ,  $C_6H_5SF_5$  (Figure 4) was found by GC – MS (Figure 2) in minor quantities estimated at less than 1% of all products (Table 1). When  $C_6H_5Cl$  was used as reactant, besides  $C_6H_5SF_5$ , the chlorinated compound  $ClC_6H_4SF_5$  was also found (Figure 2). In a low temperature plasma the dissociation of  $CF_3SF_5$  follows different routes. Dissociation into  $CF_3\cdot$  and  $SF_5\cdot$  by rupture of the C – S bond ( $E_{diss} < 272 \text{ kJ mol}^{-1}$ )<sup>33</sup> may be the primary process which produces the radicals necessary for the final products  $C_6H_5CF_3$  and  $C_6H_5SF_5$  to be formed. The stepwise dissociation of the  $SF_5$  group in  $CF_3SF_5$  is another probable pathway which may lead to the  $SCF_3$  substituted benzenes found in all reactions where  $CF_3SF_5$  was a reactant. When using  $CF_3SF_5$  as reactant common

features in the composition of the reaction products were minor amounts of halogenated benzenes and greater numbers of compounds found in comparison to reactions with SF<sub>6</sub> as reactant. The first may well be explained by different dissociation pathways of CF<sub>3</sub>SF<sub>5</sub> which may not lead to fluorinating species.

The greater number of compounds found in reaction mixtures containing CF<sub>3</sub>SF<sub>5</sub> is the consequence of the relatively high stability of the CF<sub>3</sub>· radical which is reflected in the formation of numerous trifluoromethylated compounds. Nevertheless, the reaction of CF<sub>3</sub>SF<sub>5</sub> and C<sub>6</sub>H<sub>6</sub> produces product with by far the most simple gas chromatogram out of nine, as only one halogen, fluorine, is introduced by the reactants. The

concentrations of  $C_6H_5SF_5$ ,  $C_6H_5CF_3$  and biphenyl in the reaction products (Figure 3) were much higher when  $CF_3SF_5$  was one of reactants. When  $ClSF_5$  was used, the number of reaction products increased considerably, due to the chlorination of aromatic species, but the quantity of  $C_6H_5SF_5$  was very low.

*Reactions in the stainless steel reactor.* The reactions of  $SF_6$  and benzene in the stainless steel reactor at different flow rates of  $C_6H_6$ ,  $1\text{ mL min}^{-1}$  of Ar and  $3\text{ mL min}^{-1}$  of  $SF_6$  showed that a higher flow rate of  $C_6H_6$  causes fewer products to form and in lower quantities. More volatile products *i.e.*  $SiF_4$ ,  $SOF_4$  and  $SO_2F_2$ , along with unreacted  $SF_6$  were observed in traces; they originate from reactions of sulfur fluorides with the quartz windows of the stainless steel reactor.

**Table 2.** Reaction products obtained in the stainless steel reactor

Reactants	Reaction products
$SF_6 + C_6H_6$	$C_6H_5C_6H_5$ , $C_6H_5C_2H_2C_6H_5$ , $C_6H_5C_6H_4F$ , $C_6H_5CH_2C_6H_5$ , $C_6H_5CH_3$ , $C_6H_5C_2H_5$ , $C_6H_5SF_3$ , $S_8$ , $C_6H_5SF_5$
$CF_3SF_5 + C_6H_6$	$C_6H_5C_6H_5$ , $C_6H_5C_6H_4F$ , $C_6H_5CF_3$ , $C_6H_5SCF_3$ , $C_6H_4F_2$ , $C_6H_3F_2CF_3$ , $C_6H_5SF_5$
$ClSF_5 + C_6H_6$	$C_6H_5C_6H_5$ , $ClC_6H_4SC_6H_4Cl$ , $C_6H_4F_2$ , $C_6H_4FCl$ , $C_6H_5Cl$ , $C_6H_3F_2Cl$ , $C_6H_4ClC_4H_9$ , $C_6H_5SO_2Cl$ , $C_6H_5SF_5$

Again, pentafluorosulfanylbenzene appeared in traces in all reaction products. An interesting feature is the appearance of  $FC_6H_4SF_5$  in the reaction products at a  $C_6H_6$  flow rate of  $3.5\text{ mL min}^{-1}$ , along with large quantities of biphenyl. Though the concentration of  $C_6H_5SF_5$  in the reaction products proved to depend on the reagents used and on the flow rates of reactants, no attempt was made to improve the yield of  $C_6H_5SF_5$  by optimisation of the experimental conditions. However, it is very likely that the yield would increase dramatically by the use of  $S_2F_{10}$ , the most clean source of  $SF_5\cdot$  radicals, but this was avoided in the present study due to its extremely high toxicity.<sup>34</sup>

### Conclusions

Dissociation–decomposition of SF<sub>6</sub> gas in a low temperature plasma was determined to be in the range of 50% to 60%. Products of reactions of the sulfur fluorides SF<sub>6</sub>, CF<sub>3</sub>SF<sub>5</sub> and ClSF<sub>5</sub> with C<sub>6</sub>H<sub>5</sub>, C<sub>6</sub>H<sub>5</sub>Br and C<sub>6</sub>H<sub>5</sub>Cl in a low temperature plasma consisted mainly of halogenated benzenes. Pentafluorosulfanylbenzene was found in all cases in minor quantities but for the preparation of pentafluorosulfanylbenzenes conventional methods are preferred.

### Povzetek

Žveplovi fluoridi SF<sub>6</sub>, ClSF<sub>5</sub> in CF<sub>3</sub>SF<sub>5</sub> v nizkotemperaturni radiofrekvenčni plazmi reagirajo s C<sub>6</sub>H<sub>6</sub>, C<sub>6</sub>H<sub>5</sub>Br in C<sub>6</sub>H<sub>5</sub>Cl. Zaradi postopne disociacije žveplovih fluoridov pride do fluoriranja benzenov. V vseh reakcijskih produktih je bil dokazan C<sub>6</sub>H<sub>5</sub>SF<sub>5</sub> v manjših količinah, v nekaterih tudi BrC<sub>6</sub>H<sub>5</sub>SF<sub>5</sub> ali ClC<sub>6</sub>H<sub>5</sub>SF<sub>5</sub>, skupaj s številnimi halogeniranimi benzeni, kadar sta bila uporabljena reaktanta C<sub>6</sub>H<sub>5</sub>Br ali C<sub>6</sub>H<sub>5</sub>Cl.
