Abstract

Three copper(II) coordination compounds with vanillinate ion trans-[Cu(C₆H₆O₇)(H₂O)]·2H₂O 1, [Cu(C₆H₅O₇)(H₂O)]·2H₂O 2 and [Cu(C₆H₅O₇)(H₂O)]·2H₂O 3 were synthesized and characterized. The structure analysis of air-unstable complex 1 reveals trans arrangement of two vanillinate ligands around copper(II) ion, coordinated via methoxy (Cu–O₃ 2.3266(14) Å) and deprotonated hydroxy group (Cu–O₄ 1.9383(13) Å). In the octahedral coordination sphere, two water molecules are also present (Cu–Ow1 2.0113(15) Å). Copper(II) ions in air-stable vanillinate complexes 2, 3 and 1a ([Cu(C₆H₅O₇)(H₂O)]·2H₂O, partially decomposed 1), that show very similar vibrational and electronic spectra, represent isolated paramagnetic centers (µeff > 1.73 BM). The most significant differences in IR spectra are above 3000 cm⁻¹ for 1a (partial decomposition of 1 and different H-bonding), and in electronic spectra for non-typical orange coloured 2 with respect to yellow-green 1a and 3.

Key words: copper, vanillin, lignin, model, structure

Introduction

Application of copper compounds in wood protection, due to their fungicidal activity, is known for a long time. Although such protection is very commonly used, the mode of copper action and its way of binding to wood are still not known accurately. Possible binding site for copper is lignin, due to several different oxygen atoms present in its structure and its high abundance in wood. Lignin is composed of several different subunits of phenylpropane derivatives, mutually connected in many ways. Exact structure is not known, since all attempts of isolation revealed some changes in the basic structure. In this aspect, the lignin model compounds and their copper complexes seem to be a suitable basis for research of copper to wood interactions. So far, a few vanillinate (= 4-formyl-2-methoxyphenolate) copper complexes with additional nitrogen ligands and one vanillic acid anion (= 4-hydroxy-3-methoxybenzolate) copper complex were described (Scheme 1). In this paper, several new copper(II) complexes with lignin model compound vanillin are presented and described by structural, magnetic and spectroscopic parameters.

Results and discussion

Description of the crystal structure of trans-diaquaabis(vanillinate(O,O'))copper(II) dihydrate 1. The copper(II) ion in [Cu(C₆H₅O₇)(H₂O)]·2H₂O (1) is surrounded by two deprotonated vanillinate ions and two water molecules in trans orientation (Figure 1). The basal plane in an elongated octahedral chromophore CuO₆ is composed of two deprotonated hydroxy groups (Cu–O₄ 1.9383(13) Å) and two water molecules (Cu–Ow1 2.0113(15) Å). Elongated Jahn-Teller axis in the octahedron is described by two methoxy oxygen atoms (Cu–O₃ 2.3266(14) Å). Significant rhombic distortion of an octahedron is probably due to rigidity of the vanillinate ion (O₄–Cu–O₃ 76.43(5)°) and several hydrogen bonds present in the structure (Table 1). Two additional water molecules are more distant from copper ion. Each of them is hydrogen bonded to one coordinated water molecule (Ow2–H21···Ow1 2.971(3) Å) and by a pair of H-bonds (Ow2–H22···Ow2iii 2.812(3) Å) to the neighbouring non-coordinated water molecule (Figure 1). The coordinated water molecule is connected with much stronger intermolecular hydrogen bonds also to the aldehyde group (Ow1–H12···O11i 2.686(2) Å) and to the hydroxy group of the adjacent mononuclear unit (Ow1–H11···O4ii 2.650(2) Å). A projection of the mononuclear units in 1 reveals parallel layers (Figure 2). The C–O distances are similar as found in the structure of free vanillin. X-ray diffraction data of 1 were collected at 150 K, due to instability of the compound outside the solution at room temperature. As confirmed by elemental analysis, the diversity between

the XRD powder data, obtained at room temperature, and calculated via the structural data, can be ascribed to some structural rearrangements, occurring after release of two uncoordinated water molecules. This partial decomposition of 1 in air yields 1a.

Symmetry code: (i) x, ½+y, 1½–z; (ii) 1–x, 1–y, 1–z; (iii) 1–x, 1–y, 2–z;

Another two vanillinate complexes, orange [Cu(C₈H₇O₃)₂(H₂O)₂] 2 and green [Cu(C₈H₇O₃)₂(H₂O)₂]·2H₂O 3 (XRD powder pattern is different than for 1a or calculated for 1)⁹,¹⁰ are stable in air. Due to isolated paramagnetic Cu(II) centers for three vanillin compounds 1a, 2, 3 (µₑffective ~ 1.9 BM), mononuclear coordination sphere is proposed for them. The electronic spectra of almost identically coloured solutions, obtained by dissolution of differently coloured solids 1a, 2, 3 in methanol or acetonitrile, indicate that the coordinated species in all three compounds are rearranged into the same one (Figure 3). In the mull spectrum of 2, very weak d–d signal at 810 nm and much stronger shoulder at 500 nm (next to LMCT and π-π transitions in the UV region)¹¹ were observed, visible also as copper(II) non-typical orange colour. Both signals of similar intensity ratio were also found in the spectra of yellow-green 1a and 3, but at lower energies (470(sh), 675 nm 1a; 485(sh), 695 nm 3).

Figure 1. The hydrogen-bonding pattern in the structure of 1.

Figure 2. A parallel wave-like orientation of the mononuclear units in the structure of 1. Hydrogen atoms are omitted for clarity.
The electronic spectra of the α-[Cu(C₅H₇O₆)₂(H₂O)]·2H₂O were used for the visible light region spectra. Due to very low intensity of the d-d transition signals, higher concentration of the solutions (200–400 nm, 3.0×10⁻⁴ M; 400–860 nm, 3.0×10⁻³ M) and higher density of the suspensions were used for the visible light region spectra.

Air-stable complexes 2 and 3 show similar broad IR signal in the 3400-3100 cm⁻¹ region, while for 1a a sharp band at 3445 cm⁻¹ was observed. The origin of these bands are probably in water molecules, since the hydroxy group was found deprotonated in 1, 2, and 3. Strong similarities in the spectra of 1a, 2, 3 and free vanillin were found in 1700-1400 cm⁻¹ region, where also the ν(C=O) aldehyde band at 1650 cm⁻¹ was found, indicating non-coordination via the aldehyde group.

To correlate three very similar formulations 1-3 more unambiguously, in the continuation of this work we will try to obtain single crystals of the compounds 2 and 3 for structural characterization of the complexes, together with the EPR characterization of all three species.

Conclusions

Three copper(II) complexes with lignin model compound vanillin were synthesized. The structure of [Cu(C₅H₇O₆)₂(H₂O)]·2H₂O 1 reveals didentate coordination of vanillinate via methoxy oxygen atom and deprotonated hydroxy oxygen atom in mononuclear species, as observed in other copper vanillinate complexes, confirming the bonding role of copper to lignin. In all Cu-vanillinate complexes found in the literature, additional nitrogen donor ligands are also present. This is the most significant difference with regard to compounds 1-3 described here, where only oxygen donor ligands are found. Since these complexes were synthesized from nitrogen ligand free aqueous solutions, the nitrogen ligands are not necessary for copper coordination at lignin models.

Experimental

Materials: All starting compounds and solvents were used as purchased, without any further purification.

X-ray crystallography: The crystal data were collected on Kappa CCD Nonius diffractometer with graphite monochromated Mo Kα radiation. The structure was solved by direct methods, and the figures were drawn using PLATON. Refinements were based on F² values and done by full-matrix least-squares with all non-H atoms anisotropic. Hydrogen atoms were located from a ΔF synthesis and included in the refinement at calculated positions and with the isotropic displacement parameters of 1.2 times the Ueq value of their respective attached heavy atom, 1.5 times for the methyl hydrogens. Crystal data: C₅₉H₂₂CuO₁₈, 1, F₁ = 437.89, monoclinic, a = 4.90380(10), b = 19.6635(5), c = 9.4786(2) Å, β = 92.0300(10), V = 913.41(4) Å³, T = 293(2) K, space group P2₁/c (No. 14). Z = 4, µ(Mo Kα) = 1.249 mm⁻¹, 3814 reflections measured, 1818 unique (Rint = 0.0326) which were used in all calculations. The final wR(F²) was 0.0395 (all data).

Physical measurements: Metal analysis was carried out electrogravimetrically with Pt electrodes. C, H analysis was performed with a Perkin Elmer, Elemental Analyzer 2400 CHN. Interplanar spacings were obtained by the Guinier camera (Huber), Cu Kα radiation. The magnetic susceptibility of the substances was determined at room temperature by powdered samples with a Sherwood Scientific MSB-1 balance. Diamagnetic corrections were estimated from Pascal’s constants. Infrared spectra were measured on mineral oil mulls, using a Perkin-Elmer FT-IR 1720X spectrometer. Electronic spectra were recorded as nujol mulls with a Perkin-Elmer UV/VIS/NIR spectrometer Lambda 19.

Synthesis: trans-[Cu(C₅H₇O₆)₂(H₂O)]·2H₂O (1); [Cu(C₅H₇O₆)₂(H₂O)] (1a): 0.320 g of [Cu₂(O₂CCH₃)₃(H₂O)] was dissolved in 10.0 mL of water while stirring and slow heating. The solution was added to 0.244 g of vanillin. Yellow-green needle-like crystals of 1 were filtered off after three days and dried in air for a day, when the crystals dimed (1 change to 1a). The crystal structure was obtained from undeayed single crystal of 1, frozen immediately after removing from the mother liquid, while for the other characterization methods, the dried sample of 1a was used. Yield 30%. Anal. Caled for C₅₉H₂₂CuO₁₈ (1a): C 47.8, H 4.51, Cu 15.8. Found: C 47.2, H 4.34, Cu 15.7. UV-Vis (CH₃CN)

\[ [\text{Cu}([\text{C}_6\text{H}_5\text{O}_2])_2(\text{H}_2\text{O})_2] \] (2); \[ [\text{Cu}_2([\text{O}_2\text{CCH}_3])_3(\text{H}_2\text{O})_3] \] (0.160 g) was dissolved at room temperature in 10.0 mL of acidified water (one drop of glacial acetic acid). The solution and solid vanillin (0.244 g) were slowly heated and dissolved in \text{~5} seconds. Orange crystals of 2 were filtered off next day and dried in air for a day. If the temperature is not high enough, the dissolution might take longer, while too high temperature (over 100 \degree \text{C}) partly change vanillin (black particles), both leading in partial precipitation of compounds 1 and 2 (after two days mostly 1 was present). Yield 20\%. Anal. Calcd for C_{16}H_{12}CuO_7; C 47.8, H 4.51, Cu 15.8. Found: C 47.5, H 4.33, Cu 15.7. Tri bakrove(II) koordinacijske spojine z vanilinatnim ionom trans-[Cu([C_6H_5O_2])_2(H_2O)_2]2H_2O 1, [Cu([C_6H_5O_2])_2(H_2O)_2] 2 in [Cu([C_6H_5O_2])_2(H_2O)_2]2H_2O 3 so bile sintetizirane in karakterizirane. Strukturna analiza na zraku neobstojne spojine 1 pokaže trans usmeritev dveh vanilinatnih ligandov okoli bakrovega(II) iona, koordiniranega preko metoksik (Cu–O 3.2266(14) \AA) in deprotonirane hidroksi skupine (Cu–O 3.9385(13) \AA). V oktaedrični koordinacijski sferi sta prisotni tudi dve molekuli vode (Cu–O 2.0113(15) \AA). V spojinah 2, 3 in 1a (([Cu([C_6H_5O_2])_2(H_2O)_2]; 1a po delnem razpadu), ki so na zraku obstojne in imajo podobne vibracijske in elektronske spektrine, predstavljajo bakrov(II) ioni izolirane paramagnetna jedra (\mu_{\text{eff}} > 1.73 \text{ BM.}) Obdana s podobnimi koordinacijskimi sfernami. V IR spektri ni opazno razlike v območju nad 3000 cm\(^{-1}\) pri 1a (delno razpadla 1 ter spremenjene vodikove vezi), in v elektronskem spektru spojine 2, ki je, v primerjavi z rumeno zeleno obarvanima spojinama 1a in 3, obarvano netipično oranžno.
