Abstract

The crystal structures of two novel compounds, KSr6Sc(SiO4)4 and Rb5In(MoO4)4, were determined from single-crystal X-ray diffraction data collected at room temperature. Both compounds have been synthesised by the flux growth technique in the course of a research project on new micro- and nanoporous alkali-M3+ silicates. KSr6Sc(SiO4)4 represents a new structure type and the first silicate containing decorated kröhnkite-like octahedral-tetrahedral chains. It is orthorhombic and crystallises in Pnma, with a = 19.137(4), b = 11.197(2), c = 7.125(1) Å, V = 1526.7(5) Å³, Z = 8.

Rb5In(MoO4)4 has space group P21/c with a = 11.391(2), b = 7.983(2), c = 11.100(2) Å, α = 113.74(3)°, V = 924.0(3) Å³, Z = 2. It is isotypic with RbEr(MoO4)4. The topologies of both compounds are characterised by isolated infinite decorated kröhnkite-like chains that are built from either ScO6 or InO6 octahedra corner-linked and decorated by SiO4 or MoO4 tetrahedra. These chains are separated by alkali or alkaline earth metals. A detailed comparison to the few other compounds based on decorated kröhnkite-like chains, viz. Ba2Ca(HPO4)2(H2PO4)2, CsM3+(H1.5AsO4)2(H2AsO4) (M3+ = Ga, Cr), CsAl(H2AsO4)2(HAsO4), K(H2O)M3+(H1.5AsO4)2(H2AsO4) (M3+ = Fe, Ga, In) and K5In(MoO4)4 is given.

Keywords: Decorated kröhnkite-like chains, rubidium indium molybdate, strontium potassium scandium silicate, flux growth, single-crystal X-ray diffraction

1. Introduction

Kröhnkite-type chains (Figure 1) are infinite isolated octahedral-tetrahedral chains formed from the ladder-like corner-linkage of MO6 octahedra and XO4 tetrahedra. They are named after the mineral kröhnkite, Na2Cu(SO4)2·2H2O, in which this type of chain was first described.1 Kröhnkite-type chains are encountered in a large number of natural and synthetic compounds in different orientations and topological arrangements. Fleck, Kolitsch and coworkers provide a detailed classification and reviews of all compounds containing kröhnkite-type or kröhnkite-like chains (the latter are topologically very similar to, but not identical to kröhnkite-type chains sensu strictu), and decorated variants of the latter (the two ‘free’ apices of the MO6 octahedra are further decorated with one or two XO4 tetrahedra; only very few examples of such variants are known).2–6 The mentioned classification encompasses (generally hydrated) XO4 oxysalts, where X = P5+, As5+, S6+, Se6+, Cr6+, Mo6+, W6+.

During a systematic research for new micro- and nanoporous silicates in the system M9+−(M9+−)M15+−Si−O (M9+ = Na, K, Rb, Cs; M15+ = Sr, Ba; M15+ = Sc, V, Cr, Fe, In, Y, Yb, Gd) with the help of high-temperature flux growth syntheses, two novel compounds containing decorated kröhnkite-like chains, KSr6Sc(SiO4)4 and Rb5In(MoO4)4, were grown from molybdate-based flux solvents.7,8 During this research project, more than 30 new crystalline compounds (including isotypic compounds)

Wieczorek et al.: Flux Syntheses and Crystal Structures ...
with 12 novel structure types have been studied in detail by single-crystal X-ray diffraction methods, supplemented by chemical analyses and Raman spectroscopy. The following novel silicates are described and summarised in a PhD Thesis completed at the University of Vienna:\textsuperscript{7} BaKREESi$_2$O$_7$ (REE = Y, In, Sc) and isotypic SrKREE$_4$Si$_5$O$_{17}$ (REE = Yb, Sc) and isotypic SrK$_4$Mo$_4$O$_{13}$, RbFe(MoO$_4$)$_2$ and isotypic Rb$_5$In(MoO$_4$)$_4$ (REE = Y, In, Sc) (P2$_1$/c),\textsuperscript{12} Ba$_2$Gd$_2$Si$_4$O$_{13}$ (M1$^+$ = K, Rb, Cs) (P2$_1$/m)\textsuperscript{13,14} BaY$_4$Si$_5$O$_{17}$ (REE = Yb, Sc) and isotypic SrKSc$_2$Si$_2$O$_7$ (isotypic to BaKYSi$_2$O$_7$), small colourless pseudohexagonal crystals of SrKSc$_2$O$_7$ (Pnma) and isotopic Rb$_7$YSi$_3$O$_9$.

The flux syntheses also yielded several, partly new molybdates as reaction by-products, e.g., novel Rb$_7$K$_3$Mo$_4$O$_{13}$, K$_2$Y(MoO$_4$)$_4$, Rb$_5$In(MoO$_4$)$_4$ and isotypic Rb$_5$Fe$_2$Mo$_4$O$_{13}$, which is isotypic to BaKYbSi$_2$O$_7$, small colourless pseudohexagonal crystals of SrKSc$_2$O$_7$, which is isotypic to BaKYbSi$_2$O$_7$, and Sr$_3$(Si$_3$O$_9$).

In the present paper we report the syntheses and the crystal structures (determined from single-crystal X-ray diffraction data) of K$_3$Sr$_6$Sc(SiO$_4$)$_4$ and Rb$_5$In(MoO$_4$)$_4$, and we discuss and compare the decorated kröhnkite-like chains in their atomic arrangements with those of all other presently known compounds containing such chains.

2. Experimental

2.1. Syntheses

The flux growth experiments were conducted in a Naber high-temperature furnace in air using platinum crucibles at $T_{\text{max}} = 1150$ °C. Small, colourless, pseudo-tetragonal prisms of K$_3$Sr$_6$Sc(SiO$_4$)$_4$ were grown from a MoO$_3$ flux containing dissolved reagent-grade starting materials of K, Sr, Sc and Si (experimental parameters: 1.0014 g K$_2$CO$_3$, 1.0001 g Sr(OH)$_2$.3H$_2$O, 0.1245 g Sc$_2$O$_3$, 0.2118 g SiO$_2$, 1.0010 g MoO$_3$). The Pt crucible filled with an intimate mixture of the starting materials was heated up during 12 h to 1150 °C, followed by a holding time of 3 h, and cooling during 125 h (2 K/h) to 900 °C, at which point the furnace was switched off. The reaction products were washed in distilled water, filtered and dried in air. This synthesis yielded three other reaction products, namely pseudo-octahedral crystals of SrKSc$_3$Si$_4$O$_7$ (Cc), which is isotypic to BaKYbSi$_3$O$_7$, small colourless pseudohexagonal plates of SrKSc$_3$Si$_4$O$_7$, which is isotypic to BaKYbSi$_3$O$_7$ and Sr$_3$(Si$_3$O$_9$).

Small colourless prisms of Rb$_5$In(MoO$_4$)$_4$ were obtained as a by-product during a flux growth experiment for which the following starting mixture of reagent-grade starting material was used: 1.5004 g RbF, 0.1824 g In$_2$O$_3$, 0.1019 g SiO$_2$ and 1.7733 g MoO$_3$. The used temperature programme was: heating up during 4 h to 1150 °C, holding time 3 h, cooling for 166.6 h (1.2 K/h) to 900 °C, after which the furnace was switched off. The crystals were accompanied only by one additional phase, In$_2$O$_3$.

2.2. Data Collection and Structure Solution

The crystal structures of K$_3$Sr$_6$Sc(SiO$_4$)$_4$ and Rb$_5$In(MoO$_4$)$_4$ were determined from single-crystal X-ray diffraction data obtained from selected crystal fragments of good diffracting quality. Measurements were made with a Nonius KappaCCD four-circle X-ray diffractometer, equipped with a capillary optics collimator (for further details on data collection strategies and data processing see Table 1). The intensity data were processed with the Nonius program suite DENZO-SMN\textsuperscript{19} and corrected for Lorentz, polarization and background effects. Absorption was corrected according to the multi-scan method. The program SHELXS-97 was used for the solution of the crystal structures, employing direct methods. The structure

$^*F_0 > 4σ(F_0)$

$^\dagger w = 1/\sigma^2(F_0^2) + (a \times P^2 + b \times P); P = [\text{max}(0, F_0^2) + 2 \times F_0^2]/3$
models were refined by standard full-matrix least-squares techniques on $F^2$ using SHELXL-97.$^{20}$

For the final refinement step of the structure model of $\text{Rb}_5\text{In(MoO}_4)_4$, the atomic coordinates of isotypic $\text{Rb}_5\text{Er(MoO}_4)_4$ were used as a starting model.$^{21}$

The final cycles of least-squares refinement for $\text{Ksr}_x\text{Sc(SiO}_4)_y$ gave the residuals $R(1(F)) = 3.55\%$ and $wR^2(2(F^2)) = 7.97\%$ using 1863 reflections with $F_o > 4\sigma(F_o)$ and 146 parameters. For $\text{Rb}_5\text{In(MoO}_4)_4$ the residuals are: $R(1(F)) = 2.27\%$, $wR^2(2(F^2)) = 5.72\%$ for 3697 reflections with $F_o > 4\sigma(F_o)$ and 120 parameters (see Table 1). The final difference Fourier maps were fairly smooth and showed a minimum of $-1.18$ e/$\text{Å}^3$ (Sr position) and a maximum of 1.86 e/$\text{Å}^3$ (close to the K position) for $\text{Ksr}_x\text{Sc(SiO}_4)_y$. Corresponding values for $\text{Rb}_5\text{In(MoO}_4)_4$ were $-1.80$ and $1.62$ e/$\text{Å}^3$, respectively (both close to Rb positions). The final positional and displacement parameters of $\text{Ksr}_x\text{Sc(SiO}_4)_y$ and $\text{Rb}_5\text{In(MoO}_4)_4$ are given in Tables 2 and 5. Anisotropic displacement parameters are listed in Tables 3 and 6. Selected interatomic distances and calculated bond-valence sums (v.u.) for the coordination polyhedra are presented in Tables 4 and 7. All figures were drawn using the program ATOMS 5.1 version.$^{22}$

3. Results and Discussion

3.1. Crystal Structures and Topologies

3.1.1. $\text{Ksr}_x\text{Sc(SiO}_4)_y$

$\text{Ksr}_x\text{Sc(SiO}_4)_y$ represents a novel structure type, the first K–Sr–Sc silicate and the first silicate with decorated kröhnkite-like octahedral-tetrahedral chains.

Other reported scandium silicates containing alkali and/or alkaline earth cations comprise $\text{K}_x\text{Sc(SiO}_4)_x$, $\text{K}_x\text{ScF(Si}_2\text{O}_4)_x$, $\text{BaSc}_2\text{Si}_2\text{O}_7$, $\text{SrSc}_2\text{Si}_2\text{O}_7$, $\text{Na}_x\text{Sr}_y\text{Sc}_2(\text{Si}_2\text{O}_7)(\text{SiO}_4)_2$. None of these compounds shows a close structural relation to $\text{Ksr}_x\text{Sc(SiO}_4)_y$.

The new structure type of $\text{Ksr}_x\text{Sc(SiO}_4)_y$ (Figures 2, 3) contains one octahedrally coordinated Sc site, three crystallographically non-equivalent SiO$_4$ tetrahedra, and five Sr sites, three of which are occupied by a mixture of Sr and K atoms (one with K $>$ Sr) (Table 2). The majority of these sites are located on mirror planes in $y = \frac{1}{4}$. The ScO$_6$ octahedra share all of their oxygen corners with SiO$_4$ tetrahedra, forming isolated decorated octahedral-tetrahedral chains running parallel to $[010]$, i.e., decorated kröhnkite-like chains (see Figure 2). The Sr/K atoms are located between these chains. The [8]- or [9]-coordinated Sr atoms have average Sr–O bond lengths of 2.61, 2.73 and 2.74 Å (Table 4). The average K–O bond length of the [8+2]-coordinated K atom is 2.87 Å. The average Si–O bond lengths lie within a small range from 1.62 to 1.64 Å. The isolated ScO$_6$ octahedron is only slightly distorted, with O–Sc–O bond angles ranging between 83.14° and 94.48 and between 170.9 and 177.58°. The average Sc–O bond length (2.10 Å) corresponds very well with literature values for oxidic Sc compounds (2.10 Å).$^{27}$ The bond-valence sums (BVSs) of Si atoms range between 3.86 and 4.02 v.u. (valence units). The BVSs for the Sr1 (1.84 v.u.), Sr2 (2.14 v.u.) and Sr3 (1.77 v.u.) atoms are close to the theoretical value.

In contrast, BVSs for the Sr4 (1.61 v.u.) and K5 (1.51 v.u.) atoms reflect the mixed (Sr/K) occupancies of these two sites (Table 4). We would like to point out that unrestrained occupancy refinements of the mixed Sr/K sites resulted in a nearly charge-balanced empirical formula ($\approx \text{Ksr}_x\text{Sc(SiO}_4)_y$), with 63.9 positive charges vs. 64 negative charges. For the final refinement the occupancies were slightly modified and then fixed to achieve a completely charge-balanced formula.

![Figure 2](image-url) View of $\text{Ksr}_x\text{Sc(SiO}_4)_y$ along [001], and perpendicular to the decorated kröhnkite-like octahedral-tetrahedral chains (in the central part of the figure, Sr atoms have been omitted in order to show the SiO$_4$ tetrahedra more clearly).

![Figure 3](image-url) The structure of $\text{Ksr}_x\text{Sc(SiO}_4)_y$ projected along [010], i.e., parallel to the isolated decorated kröhnkite-like octahedral-tetrahedral chains.
3.1.2. Rb$_5$In(MoO$_4$)$_4$

Rb$_5$In(MoO$_4$)$_4$ belongs to the large group of isoelectronic compounds with the general formula A$_5$M$_3^+$XO$_4$$_4$ ($A =$ Rb, K, Tl; $M^3^+ =$ REE, Bi, Fe, In; $X =$ Mo, W). Most of them crystallise in a variety of layered structure types, related to the mineral palmierite, K$_5$Pb(SO$_4$)$_2$. In contrast, Rb$_5$Er(MoO$_4$)$_4$ and isotypic Rb$_5$In(MoO$_4$)$_4$ represent a chain-based structure type, which is built from decorated kröhnkite-like chains. The crystal structure of Rb$_5$Er(MoO$_4$)$_4$ was determined by Klevtsova and Glinska-

3.1.2. Rb$_5$In(MoO$_4$)$_4$

Wieczorek et al.: Flux Syntheses and Crystal Structures ...
ya; it is monoclinic, with space group $P2/1$ and the unit-cell parameters $a = 11.44$, $b = 7.99$, $c = 11.19$ Å, $\beta = 113.3^\circ$. We point out that the crystal structure data of Rb$_5$Er(MoO$_4$)$_4$ are missing in the latest edition of the Inorganic Crystal Structure Database (ICSD). The ICDD-PDF contains a measured X-ray powder diffraction pattern of Rb$_5$In(MoO$_4$)$_4$ (PDF-entry no. 26-1367). The pattern is indexed on the basis of a monoclinic (space group not given) unit cell with $a = 18.78$, $b = 7.984$, $c = 12.30$ Å, $\beta = 91.58^\circ$, $V = 1843.56$ Å$^3$ which corresponds numerically to a $B$-centered cell with double volume as compared to the unit-cell parameters reported here ($a = 11.391$, $b = 7.983$, $c = 11.100$ Å, $\beta = 113.74^\circ$, $V = 924.0$ Å$^3$, space group $P2/1$; transformation matrix $P$- to $B$-centred cell $[^{10} -^{10} 1^{0}]$). A comparison of the powder diffraction data reported in PDF-entry no. 26-1367 with those calculated for the compound described in this work shows that all

Bond-valence sums (v.u.) for the oxygen atoms O1 to O10 are as follows: O1 = 1.94, O2 = 2.10, O3 = 2.09, O4 = 1.86, O5 = 1.89, O6 = 2.01, O7 = 1.83, O8 = 1.90, O9 = 2.01, O10 = 1.95.

Figure 4. View of Rb$_5$In(MoO$_4$)$_4$ along [001], parallel to the decorated kröhnkite-like octahedral-tetrahedral chains.

Wieczorek et al.: Flux Syntheses and Crystal Structures

*Bond-valence calculations are based on parameters of Brese & O’Keeffe and for Sc atoms, on Brown (updated values from webmirrors/i_d_brown). Bond-valence sums for the mixed Sr/K sites Sr4 and K5 were calculated taking into account the respective occupancies (see Table 2).

**Not used for calculation of mean distances and BVSs.
strong and medium strong reflections of Rb$_5$In(MoO$_4$)$_4$ appear in the pattern. However, there are a number of additional strong reflections reported that clearly do not belong to the powder diffraction pattern of Rb$_5$In(MoO$_4$)$_4$.

The asymmetric unit of Rb$_5$In(MoO$_4$)$_4$ contains one In site, three Rb, two Mo and eight O sites. Two atoms, Rb1 and In, lie on special positions, whereas all remaining atoms are in general positions. The main building unit of its crystal structure (see Figures 4, 5) is a decorated kröhnkite-like [100] chain built from a distorted InO$_6$ octahedron corner-linked by MoO$_4$ tetrahedra and decorated by additional MoO$_4$ tetrahedra. These chains are separated in different directions by three non-equivalent Rb atoms. A somewhat layered character of the atomic arrangement parallel to (100) is evident from the view in Figure 5. The InO$_6$ octahedra are only slightly distorted with an average In–O bond length of 2.136 Å and O–In–O bond angles between 81.01 and 99.33 and between 156.08 and 178.74°. The Rb atoms are coordinated by eight or ten O atoms with average Rb–O bond lengths of 3.026 Å (for [8]–coordination), and 3.093 and 3.120 Å (for [10]–coordination).

According to the classification of molybdates with composition A$_5$M$^{3+}$(MoO$_4$)$_4$ (A = K, Rb; M$^{3+}$ = REE, Y, In, Sc, Fe, Al, Bi) by Lazoryak and Efremov, Rb$_5$Er(MoO$_4$)$_4$ and isotypic Rb$_5$In(MoO$_4$)$_4$ adopt structure type VII. This type is structurally similar to type V adopted by K$_5$M$^{3+}$(MoO$_4$)$_4$ (M$^{3+}$ = Tm–Lu, In, Sc), and represented by K$_5$In(MoO$_4$)$_4$ discussed below.

3.2. Comparison With Other Compounds Based on Decorated Kröhnkite-like Octahedral-Tetrahedral Chains

As already mentioned in the introduction, the kröhnkite-type chain sensu strictu is encountered in a fairly large number of compounds. In contrast, there exist only few compounds containing decorated kröhnkite-like chains. Figure 6 compares the chain units of nine known and two new compounds with decorated kröhnkite-like chains. All these compounds contain more or less distorted MO$_6$ octahedra linked and decorated by the XO$_4$ tetrahedra. However, there are distinct differences concerning both linkage and orientation of XO$_4$ tetrahedra with respect to the octahedra.

In K$_5$Sc(SiO$_4$)$_4$ (Figure 6a) and the protonated phosphate compound Ba$_2$Ca(HPO$_4$)$_2$(H$_2$PO$_4$)$_2$, the two decorating tetrahedra are attached to the trans apices of the MO$_6$ octahedra. Specifically, in K$_5$Sc(SiO$_4$)$_4$ two Si$_3$–centred tetrahedra corner-link neighbouring octahedra, whereas the two remaining Si1– and Si2–centred tetrahedra only decorate the chain. Although the overall topo-

</table>
logy of the decorated chains in both compounds is identical, the decorating P1–centred tetrahedra in Ba2Ca(HPO4)2(H2PO4)2 are considerably tilted with respect to the chain direction, and the chain is somewhat corrugated (see Figure 6b).

In Rb5In(MoO4)4 (Figure 6c) the chain is formed by a different octahedral-tetrahedral linkage scheme: Mo1–centred tetrahedra link the InO6 octahedra alternately in a horizontal and vertical plane, whereas the two Mo2–centred decorating tetrahedra are attached to the cis apices of the InO6 octahedra. This scheme results in a slightly wavy character of the chain.

Bond-valence sums (v.u.) for the oxygen atoms O1 to O8 are as follows: O1 = 2.07, O2 = 2.03, O3 = 1.98, O4 = 2.02, O5 = 1.86, O6 = 2.11, O7 = 1.94, O8 = 2.14

*Bond–valence calculations are based on parameters of Brese & O’Keeffe.29 ** Not used for calculation of mean distances and BVSs.

The chain in K$_5$In(MoO$_4$)$_4$ (Figure 6d) is related to that in Rb$_5$In(MoO$_4$)$_4$, but considerably more distorted. The linkage of the InO$_6$ octahedra by Mo2– and Mo4–centred tetrahedra in a twisted sequence, and the cis decorating Mo1– and Mo3–centred tetrahedra result in a distinct zigzag-like character of the chain.

In the protonated arsenate compounds CsM$_{1.5+}$-(H$_5$$_{1.5}$AsO$_4$)$_2$(H$_2$$_2$AsO$_4$) (M$^{3+}$ = Ga, Cr), CsAl(H$_2$AsO$_4$)$_2$(HAsO$_4$) and K(H$_2$O)$_2$M$^{3+}$(H$_1.5$AsO$_4$)$_2$(H$_2$AsO$_4$) (M$^{3+}$ = Fe, Ga, In) described by Schwendtner and Kolitsch,36–38 all AsO$_4$ tetrahedra are involved in the linkage system forming the chain, i.e., each AsO$_4$ tetrahedron corner-links
two $MO_6$ octahedra (see Figure 6 e-g). The overall topology of the chains in these arsenates is identical. It is probable that this chain type will also be found in protonated phosphates.

4. Conclusions

The present work demonstrates that decorated kröhnkite-like chains are not only encountered among arsenates, phosphates and molybdates, but also in silicates, with $KSR_6Sc(SiO_4)_4$ being the first such example. A comparison of all presently known compounds containing decorated kröhnkite-like chains reveals, firstly, different systems of corner-linkage forming the chains, and, secondly, different roles of additional tetrahedra (some only play a decorating role, while others provide an additional corner-linkage along the chain direction).

Povzetek

Z metodo rentgenskeh difrakcij sta bili pri sobni temperaturi določeni kristalni strukturi dveh novih spojin KSr5Sc3(SiO4)5 in RbIn(MoO4)2. Obe spojini sta bili sintetizirani iz fluksa pri študiju novih mikro in nanoporoznih alkalijskih-M3+ silikatov. KSr5Sc3(SiO4)5 predstavlja nov strukturni tip in je to prvi silikat, ki vsebuje deformirane kröhnkitu podobne verige.
